## Markov Decision Process

#### Definition

A Markov Decision Process is a tuple  $(\mathcal{S}, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma)$ 

- $\mathcal{S}$  is a (finite) set of states
- $\bullet \ \mathcal{A}$  is a finite set of actions
- $\mathcal{P}$  is a transition probability matix

$$\mathcal{P}^{a}_{ss'} = \mathbb{P}[S_{t+1} = s' | S_t = s, A_t = a]$$

•  $\mathcal{R}$  is a reward function :

$$\mathcal{R}_s^a = \mathbb{E}[R_{t+1}|S_t = s, A_t = a]$$

•  $\gamma$  is a discount factor,  $\gamma \in [0,1]$

Model-Free Control <sup>6</sup>

May 25, 2019 4 / 31

For most problems, either:

- MDP is unknown, but experience can be sampled
- MDP is known, but is too big to use, execpt by samples (Go)

# On and Off-Policy learning

**On-policy** learning

- "Learn on the job"
- $\bullet$  Learn about policy  $\pi$  from experience sampled from policy  $\pi$

Off-policy learning

- "Look over someone's shoulder"
- $\bullet$  Learn about policy  $\pi$  from experience sampled from policy  $\beta$
- $\beta$  sometimes called behaviour policy

## Greedy policy improvement

• Greedy policy improvement over V(s) requires model of MDP

$$\pi'(s) = arg \max_{a \in A} R^a_s + P^a_{ss'} V(s')$$

• Greedy policy improvement over Q(s, a) is model-free

$$\pi'(s) = rg \max_{a \in A} Q(s, a)$$

DOROZHKO Anton (Novosibirsk State Unive

### $\epsilon\text{-}\mathsf{Greedy}$ Exploration

- Simple idea for continual exploration
- All actions are tried with p > 0

$$\pi(a|s) = egin{cases} \epsilon/|A| + 1 - \epsilon & a^* = arg \max_{a \in A} Q(s, a) \ \epsilon/|A| & otherwisex \end{cases}$$

DOROZHKO Anton (Novosibirsk State Unive

### $\epsilon$ -Greedy Policy Improvement

#### Theorem

For any  $\epsilon$ -greedy policy  $\pi$ , the  $\epsilon$ -greedy policy  $\pi'$  with respect to  $q_{\pi}$  is an improvement,  $V^{\pi'}(s) \geq V^{\pi}(s)$ 

$$\begin{aligned} q_{\pi}(s,\pi'(s)) &= \sum_{a \in A} \pi'(a|s)q_{\pi}(s,a) \\ &= \frac{\epsilon}{|A|} \sum_{a \in A} q_{\pi}(s,a) + (1-\epsilon) \max_{a \in A} q_{\pi}(s,a) \\ &\geq \frac{\epsilon}{|A|} \sum_{a \in A} q_{\pi}(s,a) + (1-\epsilon) \sum \frac{pi(a|s) - \frac{\epsilon}{|A|}}{1-\epsilon} q_{\pi}(s,a) \\ &= \sum_{a \in A} \pi(a|s)q_{\pi}(s,a) = v_{\pi}(s) \\ &\stackrel{\text{Novosibirsk}}{\underset{\text{University}}{\overset{\text{THE REAL SCIENCE}}{\overset{\text{Constrained}}{\overset{\text{THE REAL SCIENCE}}{\overset{\text{Constrained}}{\overset{\text{Const$$

# GLIE

### Definition

Greedy in the Limit with Infinite Exploration (GLIE)

• All state-action pairs are explored infinitely many times

$$\lim_{k\to\infty}N_k(s,a)=\infty$$

• The policy converges on a greedy policy

$$\lim_{k\to\infty}\pi_k(a|s)=Q_k(s,a')$$

Example: 
$$\epsilon_k = \frac{1}{k}$$

★Novosibirsk State University PFAL SCIENCE

## GLIE MC control

- Sample episode using  $\pi$  :  $S_1, A_1, R_2, ..., S_T \in \pi$
- For each state  $S_t$  and action  $A_t$  in the episode

$$egin{aligned} & \mathcal{N}(S_t, A_t) \leftarrow \mathcal{N}(S_t, A_t) + 1 \ & Q(S_t, A_t) \leftarrow Q(S_t, A_t) + rac{1}{\mathcal{N}(S_t, A_t)}(G_t - Q(S_t, A_t)) \end{aligned}$$

• Improve policy based on new Q

$$\epsilon = \frac{1}{k}$$

$$\pi \leftarrow \epsilon - greedy(Q)$$

# MC vs TD Control

TD advantages over MC

- lower variance
- online
- incomplete sequences

Idea: use TD instead of MC

- Apply TD to Q(S, A)
- use  $\epsilon$ -greedy
- update every step

### **On-policy SARSA**

 $\begin{array}{l} \mbox{Initialize } Q(s,a), \forall s \in \mathbb{S}, a \in \mathcal{A}(s), \mbox{ arbitrarily, and } Q(\textit{terminal-state}, \cdot) = 0 \\ \mbox{Repeat (for each episode):} \\ \mbox{ Initialize } S \\ \mbox{Choose } A \mbox{ from } S \mbox{ using policy derived from } Q \mbox{ (e.g., $\varepsilon$-greedy)} \\ \mbox{Repeat (for each step of episode):} \\ \mbox{ Take action } A, \mbox{ observe } R, S' \\ \mbox{ Choose } A' \mbox{ from } S' \mbox{ using policy derived from } Q \mbox{ (e.g., $\varepsilon$-greedy)} \\ \mbox{ } Q(S,A) \leftarrow Q(S,A) + \alpha \big[ R + \gamma Q(S',A') - Q(S,A) \big] \\ \mbox{ } S \leftarrow S'; \mbox{ } A \leftarrow A'; \\ \mbox{ until } S \mbox{ is terminal} \\ \end{array}$ 

DOROZHKO Anton (Novosibirsk State Unive

May 25, 2019 19 / 31

## Convergence of SARSA

#### Theorem

Sarsa converges to the oprimal action-values function  $Q(s, a) \rightarrow q * (s, a)$ , under the following conditions:

- GLIE sequence of policies  $\pi_t(a|s)$
- Robbins-Monro step-sizes  $\alpha_t$

\*THE REAL SCIENCE

•

### n-step Sarsa

#### • n-steps return

•

$$\begin{array}{ll} n = 1 & (Sarsa) & q_t^{(1)} = R_{t+1} + \gamma Q(S_{t+1}) \\ n = 2 & q_t^{(2)} = R_{t+1} + \gamma Q(S_{t+1}) + \gamma^2 Q(S_{t+2}) \end{array}$$

$$n = \infty$$
 (MC)  $q_t^{(T)} = R_{t+1} + \gamma Q(S_{t+1}) + \gamma^{T-1} R_T$ 

• n-step Q-return

$$q_t(n) = R_{t+1} + \gamma R_{t+2} + \ldots + \gamma^{n-1} R_{t+n} + \gamma^n Q(S_{t+n})$$

• n-step SARSA updates

$$Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha(q_t^{(n)} - Q(S_t, A_t))$$

# $SARSA(\lambda)$

DOROZHKO Anton (Novosibirsk State Unive

<ロト <問ト < 目と < 目と

## **Off-Policy Learning**

- Evaluate  $\pi(a|s)$  to compute  $V^{\pi}(s)$  or  $Q^{pi}(s,a)$
- $\bullet$  While taking actions by behaviour policy  $\beta$

$$S_1, A_1, R_2, \dots, S_T \sim \beta$$

Profit ?

- Learn from humans / other agents
- Re-use previous experience from  $\pi_1$ ,  $\pi_2$ , ...,  $\pi_{t-1}$
- Learn optimal policy following exploratory policy
- Learn multiple policy followint one policy

### Importance Sampling

Estimate the expectation of a different distribution

$$\mathbb{E}_{X \sim P}[f(X)] = \sum P(X)f(X)$$
$$= \sum Q(X)\frac{P(X)}{Q(X)}f(X)$$
$$= \mathbb{E}_{X \sim Q}[\frac{P(X)}{Q(X)}f(X)]$$

DOROZHKO Anton (Novosibirsk State Unive

Image: A matched by the second sec

## Importance Sampling for Off-policy MC

- Use returns  $G_t$  from  $\beta$  to evaluate  $\pi$
- Weight  $G_t$  according to similarity between policies
- along the whole episode

$$G_t^{\pi/\beta} = \frac{\pi(A_t|S_t)}{\beta(A_t|S_t)} \frac{\pi(A_{t+1}|S_{t+1})}{\beta(A_{t+1}|S_{t+1})} \cdots \frac{\pi(A_T|S_T)}{\beta(A_T|S_T)}$$

update towards corrected return

$$V(S_t) \leftarrow V(S_t) + \alpha(G_t^{\pi/\beta} - V(S_t))$$

- Problem if  $\pi$  is not dominated by  $\beta$  (  $\beta$  is zero, when pi is non-zero )
- Increase Variance

## Importance Sampling for Off-policy TD

- use TD targets from  $\beta$  to eval  $\pi$
- use IS to weight TD target  $R + \gamma V(S')$
- only 1 IS correction

$$V(S_t) \leftarrow V(S_t) + \alpha \left( \frac{\pi(A_t|S_t)}{\beta(A_t|S_t)} (R_{t+1} + \gamma V(S_{t+1})) - V(S_t) \right)$$

- lower Var than MC IS
- Policies need to be somewhat similar over only a single step

## Q-learning

- off-policy learning of Q(s, a)
- No IS is required
- Next action  $A_{t+1} \sim \beta(.|S_t)$
- Consider alternative successor  $A' \sim \pi(.|S_t)$
- update  $Q(S_t, A_t)$  towards alternative

 $Q(S_t, A_t) \leftarrow Q(S_t, A_t) + \alpha(\mathbf{R}_{t+1} + \gamma \mathbf{Q}(S_{t+1}, A') - Q(S_t, A_t))$ 

## Off-Policy Control with Q-learning

- Improve both behabiour and target
- Target

$$\pi(S_{t+1}) = \arg \max_{a'} Q(S_{t+1}, a')$$

- Behaviour  $\beta \epsilon$ -greedy Q(s, a))
- The Q-learning target simplifies:

$$R_{t+1} + \gamma Q(S_{t+1}, A')$$
  
=  $R_{t+1} + \gamma Q(S_{t+1}, \arg \max_{a'} Q(S_{t+1}, a'))$   
=  $R_{t+1} + \max_{a'} \gamma Q(S_{t+1}, a')$ 

## Q-learning Control Algorithm

 $Q(S, A) \leftarrow Q(S, A) + \alpha(R + \gamma Q(S', A') - Q(S, A))$
